**Introduction.** Based on extensive piloting work, we adapted the Incredible Years (IY) teacher-training programme to the Jamaican preschool setting and evaluated this adapted version through a cluster-randomised trial.

**Methods.** Twenty-four community preschools in Kingston, Jamaica were randomly assigned to intervention (12 schools, 37 teachers) or control (12 schools, 36 teachers). The intervention involved training teachers in classroom management through eight full-day training workshops and four individual 1-h in-class support sessions. Outcome measurements included direct observation of teachers’ positive and negative behaviours to the whole class and to high-risk children and four observer ratings: two measures of class-wide child behaviour and two measures of classroom atmosphere. Measures were repeated at a six-month follow-up.

**Results.** Significant benefits of intervention were found for teachers’ positive [effect size (ES) = 3.35] and negative (ES = 1.29) behaviours to the whole class and to high-risk children (positive: ES = 0.83; negative: ES = 0.50) and for observer ratings of class-wide child behaviour (ES = 0.73), child interest and enthusiasm (ES = 0.98), teacher warmth (ES = 2.03) and opportunities provided to share and help (ES = 5.72). At 6-month follow-up, significant benefits of intervention were sustained: positive behaviours (ES = 2.70), negative behaviours (ES = 0.98), child behaviour (ES = 0.50), child interest and enthusiasm (ES = 0.78), teacher warmth (ES = 0.91), opportunities to share and help (ES = 1.42).

**Conclusions.** The adapted IV teacher-training programme produced large benefits to teacher’s behaviour and to class-wide measures of children’s behaviour, which were sustained at 6-month follow-up. Benefits were of a similar magnitude to those found in a pilot study of the minimally adapted version that required significantly more in-class support for teachers.

**Introduction**

School and societal violence is an enormous problem in Jamaica and the wider Caribbean and the primary prevention of violence is a national and regional public health priority (Meeks-Gardner et al. 2005). Violence is also recognised as a leading global public health...
program and makes a substantial contribution to morbidity and mortality with high social and economic costs (WHO, 2014). Juvenile delinquency and antisocial behaviour in adulthood can often be traced back to early childhood. Young children who have conduct problems (which describes a range of antisocial behaviours including oppositional, aggressive, dishonest and disruptive behaviours) are not only more likely to have continued antisocial and aggressive behaviour in later childhood and adolescence, but they are more likely to experience academic failure and early school drop-out and to engage in crime and violence in adulthood (Moffitt & Scott, 2008). Interventions to prevent and reduce conduct problems in early childhood are thus an integral component of violence prevention programmes.

Schools offer a logical setting for implementing preventative interventions for young children, and school-based violence prevention programmes show significant benefits to children’s violent and aggressive behaviour in high-income countries (Hahn et al. 2007; Wilson & Lipsey, 2007). One type of violence prevention programme involves training teachers in classroom behaviour management, (for example, how to create a nurturing and supportive classroom environment, how to prevent and manage child behaviour problems and how to promote children’s social and emotional competence), and a recent meta-analysis showed that these programs, when implemented in primary school, benefit multiple child outcomes including academic achievement, behaviour, social-emotional skills and motivation (Korpershoek et al. 2016). Benefits of such interventions have also been found in pre-primary contexts: a meta-analysis of interventions focused on training caregivers in centre-based services for preschool children found benefits to caregiver–child interaction, classroom quality and child social–emotional development (Werner et al. 2016).

Training staff in early childhood centres in low and middle-income countries (LMIC) may be particularly important given the evidence that aggression and disruptive behaviour can increase on exposure to poorer quality preschool environments (Aboud, 2006; Bernal & Fernandez, 2013). There is limited evidence of such interventions from LMIC (Baker-Henningham, 2014) where schools often have less well-trained teachers and lower levels of resources.

We conducted a pilot study of the Incredible Years (IY) teacher-training programme and a curriculum unit on social–emotional skills in Jamaican preschools and found benefits to teacher practices and classroom atmosphere (Baker-Henningham et al. 2009a) and to teacher reported behaviour of children with initial higher levels of behaviour problems (Baker-Henningham et al. 2009b). In-depth interviews with teachers showed that the intervention was acceptable to teachers (Baker-Henningham & Walker, 2009). Throughout the pilot study, we documented teachers’ engagement with the programme on an ongoing basis. During each workshop, the co-facilitator recorded information including: (i) how teachers responded to the new material, (ii) any difficulties teachers showed in understanding and performing the skills taught and (iii) teachers’ feedback on their use of strategies. The facilitator and co-facilitator also completed self and peer-evaluations of each workshop that included detailed reflections of teachers’ engagement with the material. In addition, after each in-class support session, the coach documented the strengths and needs of each individual teacher based on her own observations and her discussions with the teacher. These data, combined with the data from the qualitative and quantitative evaluation, were used to adapt the IY teacher-training programme to enhance its relevance to teachers working in low-resource settings. The content was similar to the original programme but significant adaptations were made to the materials and the method of delivery of the intervention. Further details of the rationale for adapting the programme, the source of the evidence underpinning this rationale and the nature of the adaptations made are given in Table 1. This adapted programme was evaluated, in a cluster-randomised trial in 24 preschools, for its effect on the behaviour of children who were at high risk for developing conduct problems. Significant benefits were found in terms of reduced conduct problems by independent observations [effect size (ES) = 0.42], teacher report (ES = 0.47) and parent report (ES = 0.22); increased social skills by independent observations (ES = 0.74) and teacher report (ES = 0.59) and increased school attendance (ES = 0.30) (Baker-Henningham et al. 2012).

In this paper, we report the effects of this intervention on (i) teachers’ interactions with the whole class, (ii) teachers’ interactions with children at high risk for developing conduct problems, (iii) the classroom atmosphere and (iv) the class-wide child behaviour. We also examined whether benefits are sustained at a 6-month follow-up. Finally, we compare this intervention, which has been extensively adapted to the Jamaican preschool context, to the intervention used in the previous study where only minor adaptations were made.

Methods

Study design and participants

The trial took place in 24 community preschools in inner-city areas of Kingston, Jamaica. The preschools were situated in disadvantaged, low SES areas with high levels of community violence. Community preschools cater to children aged 3–6 years and are

<tr>
<td>Video vignettes were from US schools and the classroom context was unfamiliar to the teachers (e.g. higher teacher–child ratio, more resources, better physical conditions). Significant amounts of time were spent discussing, role-playing and modelling how the strategies could be implemented in the Jamaican context.</td>
<td>Facilitator reflections on workshop. Co-facilitator notes on workshop. Coach’s notes on the in-class support sessions.</td>
<td>Make video vignettes of teachers in Jamaica preschool classrooms using appropriate behaviour management techniques.</td>
</tr>
<tr>
<td>Teachers lost concentration and focus during longer video vignettes, teachers often praised vignettes with negative practices and some video examples were very subtle and easily missed by the teachers. Teachers did not always have sufficient prior knowledge to easily grasp the strategies as presented in the original programme; some content needed to be repeated several times.</td>
<td>Facilitator reflections on workshop. Co-facilitator notes on workshop.</td>
<td>Make only short vignettes (1–2 min). Use positive role models only. Make the video vignettes very explicit. Design activities to help teachers acquire new knowledge (e.g. card-sorting activity to differentiate between good and bad instructions). Provide handouts with specific examples of how to use a particular strategy. Design role plays to introduce and reinforce new concepts. (i) Provide easy to use checklists for teachers to monitor their progress, (ii) Provide simple handouts clarifying key points and (iii) Design classroom assignments to encourage teachers to document their use of specific strategies and their effects on individual children (so teachers recognise the effectiveness of the strategies).</td>
</tr>
<tr>
<td>Teachers varied in their motivation, competence and persistence in utilising the strategies.</td>
<td>Coach’s notes on the in-class support sessions. Teacher feedback during workshop. Qualitative evaluation of pilot study.</td>
<td>Implementing the strategies was difficult in classrooms characterised by overcrowding, few resources, high noise levels and high child/staff ratios. Some teachers needed substantial assistance before they were competent at using the strategies without help. Teachers found it difficult to find time to utilise a curriculum unit on social and emotional competence containing structured lessons.</td>
</tr>
<tr>
<td>Teachers preferred to spend less time in passive activities (e.g. watching video vignettes, group discussions) and more time in active activities (e.g. role plays, group work)</td>
<td>Facilitator reflections on workshop. Co-facilitator notes on workshop. Qualitative evaluation of pilot study.</td>
<td>Reduce the number of video vignettes and the time spent on group discussion. Spend more time on active, hands-on activities (e.g. role plays and small group work)</td>
</tr>
</tbody>
</table>
Rationale for adaptation

Teachers often lacked confidence to try the strategies in their classroom without assistance and/or became disheartened if the strategies did not work as intended

Teachers found it difficult to generalise their use of the strategies to different situations in the classroom

Teachers were unaccustomed to spending time playing with children, engaging in social conversation and following children's lead. There was a strong emphasis on academic learning with little or no focus on promoting children's social and emotional skills

Some teachers needed more guidance before they could use the strategies competently and consistently

Data used

Teacher feedback during workshop.
Co-facilitator notes on workshop.
Qualitative evaluation of pilot study

Teacher feedback during workshop.
Coach's notes on the in-class support sessions
Quantitative and qualitative evaluation of pilot study
Facilitator reflections on workshop.
Coach's notes on the in-class support sessions

Adaptations to materials

Spend more time on role plays and group activities to give teachers practice using the strategies during the workshops.
Provide structured in-class support sessions that focus on modelling and prompting teachers, providing supportive feedback and assisting with problem solving
Role play using each strategy in different situations.
Provide opportunity for teachers to work in small groups to plan and practice how they will use a strategy to address different child behaviours and across different activities in the school day
Increase the time allocated to the topics 'Building positive relationships with children' and 'Praise and rewards'. Increase the length of the workshops (from 5-6 days to 8 days)

Use demonstrations and explicit teaching in addition to using the more collaborative approach advocated by the IY programme.
Sample size

The study was powered based on the primary outcome of observed child behaviour (Baker-Henningham et al. 2012). For measures of teacher’s behaviour to the whole class and classroom atmosphere, with 30 teachers per group, a cluster size of three teachers per school and assuming an intra-cluster correlation coefficient of 0.25, we could detect an intervention effect of 1 S.D. with 85% power at 0.05 level of significance. We hypothesised a large ES on these outcomes based on the results of the pilot study (see Table 2). For the measures of teacher behaviour to individual children, with 105 children per group, a
cluster size of nine and assuming an intra-cluster correlation coefficient of 0.05, we could detect an intervention effect of 0.5 S.D. with 85% power at 0.05 level of significance.

**Randomisation and masking**

Schools were randomised to an intervention or control condition at the start of the intervention year using a computer-generated randomisation sequence by an independent statistician who was blind to the identity of the schools. Children entering the 4- and 5-year-old class in the 2009–2010 academic year were recruited into the study at the end of the previous school year, prior to randomisation. Children entering the 3-year-old class were recruited in October 2009, after randomisation had occurred, by a researcher who was blind to group allocation.

**Intervention**

Intervention was implemented at the level of the cluster and involved training all teachers, teacher assistants and principals in the intervention schools using an adapted version of the IY teacher-training programme (Webster-Stratton, 2000). The adaptations for the Jamaican preschool context were based on previous formative and piloting work (Baker-Henningham & Walker, 2009; Baker-Henningham et al. 2009a; Baker-Henningham, 2011). The intervention was delivered over one school year through eight full-day training workshops and four in-class support sessions for each teacher. Four of the eight training workshops were conducted on in-service teacher-training days and the intervention teachers attended our workshop rather than attending the standard workshop of the Ministry of Education. Schools also received a small amount of educational materials (e.g. blocks, manipulatives, play doh) to facilitate their use of the strategies taught. At the beginning of the following school year, (after post-test measurements), a refresher intervention was conducted in intervention schools consisting of three additional in-class support sessions. The intervention is described in full in Table 3 using the TIDier checklist (Hoffman et al. 2014) and details of the adaptations made are given in Table 1.

Teachers in control schools attended the standard monthly training workshops provided by the Ministry of Education for all community preschool teachers and received the same educational materials at the same time as the intervention schools.

**Outcome measures**

All outcome measures involved independent observations of child and teacher behaviours. Structured observations of teachers’ behaviour to the whole class and to the target children, rating scales of class-wide child behaviour and rating scales of classroom atmosphere were completed at baseline (October–November 2009) and post-test (May–June 2010). A further round of measurements was conducted from May–June 2011 and consisted of all previous measures, except for teachers’ behaviour to the target children. All observational assessments were conducted by researchers blind to the study design, hypothesis and group allocation.

**Structured observations of teacher behaviour**

Observations were conducted over eighteen 5-min periods across one school day and event recording was used to record (1) positive teacher behaviours (use of praise, incentives, describing what children are doing and positive physical behaviours) and (2) negative teacher behaviours (critical comments, negative commands, warnings and negative physical behaviour).

The observation schedule and accompanying manual were developed and used previously in Jamaican classrooms (Baker-Henningham et al. 2009a). The results for the 18 5-min periods were summed to give the total number of each category of behaviours that occurred during 90 min of observation.

**Observations of teacher behaviour to the target children**

Observations of teacher behaviour to the target children were conducted simultaneously with observations of child behaviour (Baker-Henningham et al. 2012). Within each class, three children were observed for 5 min each on a rotational basis for a total of 15 min each day per child over 4 days, across different times of the school day giving a total of 1 h of observation per child. Event recording was used for positive behaviours to the target child (e.g. positive attention, praise, incentive) and negative behaviours (e.g. critical comment, negative command) and the results were summed to give the total in 1 h of observation. All behaviours were defined in a manual.

**Rating scales of child behaviour and the classroom atmosphere**

Two ratings of the behaviour of the children in the class as a whole: level of appropriate behaviour (e.g. no fighting or other aggressive behaviours, children are not disrupting other students), and level of interest and enthusiasm displayed by children (e.g. children are enjoying classroom activities) and two ratings of teacher’s behaviour: teacher provides opportunities for children to share and help each other and teacher warmth were developed based on scales used by the Conduct Problems Prevention Research Group (1999) and used previously in Jamaica (Baker-Henningham et al. 2009a). Ratings were completed at the end of each 5-min teacher observation period using five-point scales (1–5, where 1 is low and 5 is high). The average rating over the 18 observation periods was calculated.

**Other measures**

**Quality of the classroom environment**

The quality of the classroom environment was assessed at baseline only using three subscales from the Early Childhood Education Rating Scales – Revised (ECERS-R) (Harms et al. 1998). The ECERS is a commonly used comprehensive measure of early childhood classrooms and higher scores on the ECERS have been shown to be associated with improved child development in several studies (Mashburn et al. 2008). The following subscales were used:
The workshop facilitator completed a training protocol and self-evaluation after each workshop and the teachers completed

Table 3. An adapted version of the Incredible Years (IY) teacher-training programme

Materials and content

The IY teacher-training curriculum includes content on partnering with parents, developing positive relationships with children, using praise and rewards to motivate children, preventing and managing inappropriate behaviour and teaching social skills, problem solving and anger management in the classroom.

During the training, teachers were provided with handouts summarising the key content, cue cards and home-made bingo games to teach and reinforce content related to classroom rules, friendship skills, anger management and emotions, a small hand puppet, stickers and stamps to use as incentives, copies of ‘Happygrams’ to share good news with parents and behaviour planning forms. Each school was also provided with a small amount of educational materials (e.g. blocks, manipulatives, play dough) to facilitate their use of the strategies with the children.

Procedures

The IY teacher-training workshops include the use of videotape modelling, role plays and discussions and follow a collaborative model of training which emphasises participants applying skills and concepts to their own unique situations and engaging in individual and group problem solving. The IY curriculum activities were conducted in the morning sessions of the workshops. During the afternoon sessions, activities focussed on small group work followed by feedback to the larger group. Teachers also received practical classroom assignments to be completed after each workshop. Coaching sessions were aligned with the content covered in the previous workshop and included modelling the strategies, prompting the teacher to use them, providing supportive feedback and helping the teacher to problem-solve any difficulties that arose.

Who provided

Teacher-training workshops were conducted by the first author who has extensive experience in training teachers and health workers in behavioural interventions. In-class consultations were conducted by a psychology graduate who had experience delivering the intervention during a previous pilot study and who received ongoing supervision and support from the first author.

Where

Teacher-training workshops were conducted in a church hall in a central location in Kingston. Teachers were given a small stipend to cover transportation costs (US$2/workshop).

When, how and how much

Teachers attended eight full-day (6 h) workshops from November to April. A total of 56 intervention school staff were trained in the intervention (including teachers, principals and auxiliary staff). Four of these days were allocated in-service training days and teachers attended in two groups with 26–30 participants per group (i.e. training occurred over eight days). For the remaining four training days, one teacher at a time from each school attended workshop; teachers attended in four groups with 12–16 participants per group (i.e. training occurred over 16 days). In-class assistance and support was also provided to each intervention teacher once a month for four months (Jan–Apr) for approximately 1 h each session.

A refresher intervention was provided, (after post-test measurements), in September and October of the following school year consisting of three additional in-class coaching sessions for each teacher. These sessions were designed to reinforce key aspects of the intervention: 1st session was on preventing child behaviour problems by using good classroom organisation skills; 2nd session was on promoting positive child behaviour through positive reinforcement; 3rd session focused on promoting children’s social and emotional skills.

Adapting to context

The teacher-training programme was adapted for the Jamaican preschool context in several ways. We dedicated less workshop time to watching video vignettes followed by discussion and more time on practical activities such as role plays and group work. Role plays and group activities were designed both to teach new concepts and skills and to help teachers practice and generalise previously introduced skills. These activities were based on scenarios common in Jamaican preschools. Card-sorting activities were designed to help teachers learn unfamiliar content (e.g. sorting labelled and unlabelled praise statements). Video vignettes were mostly of Jamaican preschool classrooms, supplemented by the original vignettes as necessary. New simplified handouts and classroom assignments were prepared with content and activities reflecting the Jamaican preschool context. Furthermore, new materials and activities were added to cater to the needs of teachers, many of whom had limited training, with a particular focus on classroom organisation skills and using play and interactive activities in teaching (especially in the context of limited resources, overcrowding and high child/staff ratios). New materials and activities were also designed to help teachers to fully integrate social and emotional skills into daily teaching and learning activities. Detailed notes of teachers strengths and needs were kept during each workshop and during in-class support sessions and these notes were used to inform the content and activities in the ongoing training.

Modifications

Some modifications were made based on teachers’ individual needs during the in-class coaching sessions. For example, although the coaching was designed to support the content covered in the previous workshop, if a teacher had poor class control, the coach would work flexibly to cover basic classroom management.

How well (planned and actual)

The workshop facilitator completed a training protocol and self-evaluation after each workshop and the teachers completed workshop evaluations. All of the prescribed content was covered and teachers rated all aspects of the workshops (content, video vignettes, group leader skills and group discussion) as helpful or very helpful for each of the eight workshops. Seventy percent of teachers in the intervention group attended all eight training workshops and 95% attended at least six workshops. 89% of teacher participated in all four in-class consultations.
the variables measuring teachers’ behaviour to the target children, while the class-wide child behaviour rating was normalised by squaring.

The effect of intervention was examined using multilevel multiple regression models to take into account the hierarchical nature of the data (Hayes & Moulton, 2009). For the analyses of the effect of intervention on teacher’s behaviour to the whole class, class-wide child behaviour outcomes and ratings of classroom atmosphere at post-test, baseline score and intervention group were entered as fixed effects and school was added as a random effect. In the analyses on teacher behaviour to target children, child age and sex, baseline score and group were entered as fixed effects and school and teacher were entered as random effects. All outcomes at follow-up were at the level of the classroom/teacher; group was entered as a fixed effect and school as a random effect. All multilevel analyses were conducted with MLwiN version 2.10 (Rasbash et al. 2009).

**Results**

**Sample**

All 24 preschools were followed up at post-test and 6-month follow-up and all 73 teachers were followed up at post-test. Six teachers (8.2%) were lost at 6-month follow-up (four intervention, two control) and there were no significant differences on any outcome measures at baseline or post-test between those lost and those retained. However, teachers lost were significantly younger (p = 0.02) and had been teaching for fewer years (p = 0.006). There were no significant differences between the intervention groups at baseline although number of years teaching in current school was marginally significant (p = 0.06). (Table 5).

Few teachers were qualified teachers (9.5%) although almost a quarter were currently attending teacher-training college. The teachers had been teaching for an average of 13 years and were predominantly female (94.5%). The quality of the classrooms as measured by the ECERS was generally in the inadequate range (<3) indicating that the physical conditions of the classrooms were poor (e.g. overcrowded, inappropriate furniture) and play and learning materials were extremely limited.

**Findings**

Raw scores for all outcomes by group at baseline, post-test and 6-month follow-up are given in Table 6. There were no significant differences between the groups at baseline.

At post-test (Table 7), significant benefits of intervention were found for the number of positive and
negative teacher interactions to the whole class (positive: ES = 3.35; negative: ES = -1.29) and the number of positive and negative teacher interactions to the high-risk children (positive: ES = 0.83; negative: ES = -0.50). Furthermore, teachers in intervention classrooms were rated as being more warm (ES = 2.03) and providing more opportunities for children to work together (ES = 5.72). Significant benefits of

intervention were also found for class-wide measures of child behaviour including the level of appropriate child behaviour (ES = 0.73) and children’s interest and enthusiasm (ES = 0.98).

At 6-month follow-up (Table 8), significant benefits to all measures were sustained. Intervention teachers continued to have significantly more positive interactions (ES = 2.70) and fewer negative interactions (ES = −0.98) with the whole class and were rated significantly higher on warmth (ES = 0.91) and on provision of opportunities for children to share and help each other (ES = 1.42). The ratings of class-wide child behaviour showed significant benefits to the level of appropriate behaviour (ES = 0.5) and the level of interest and enthusiasm (ES = 0.78).

**Comparison to pilot study**

Table 2 compares the context, intensity, satisfaction and benefits of the current study with a pilot study we conducted previously. In the pilot study, the IY teacher-training intervention was implemented with few adaptations, unlike in the current study in which significant changes were made. The proportion of trained teachers and class sizes were similar in both studies. The schools in the pilot study scored 0.43 S.D. higher on the space and furnishings subscale of the ECERS and 1.25 S.D. higher on the activities subscale indicating a greater level of resources. However, ECERS scores for both studies were in the minimal range. The intervention used in the pilot study was more intensive and included seven full-day workshops and a total of 21 in-class support sessions with each teacher with 14 of these also working directly with the children teaching a curriculum unit on social and emotional skills (in collaboration with the teacher); in the current study the number of workshops was similar (8 full-day workshops) but teachers received only four in-class support sessions. In both the pilot study and the current study, the intervention was acceptable to teachers as shown by attendance and satisfaction ratings and large benefits were found to teacher behaviour and class-wide child behaviour.

**Discussion**

An adapted version of an evidence-based programme aimed at training teachers in appropriate classroom management techniques in order to reduce child conduct problems and promote child competencies led to large benefits to Jamaican preschool teachers’ behaviour to the whole class and to children at high risk for developing conduct problems, to class-wide child behaviour and to classroom atmosphere. These benefits were sustained at 6-month follow-up.

The study shows that professional development training in classroom behaviour management for preschool teachers in LMIC has the potential to make large improvements to teachers’ behaviours resulting in a more emotionally supportive classroom environment and reduced harsh punishment by teachers for all children and improved class-wide child behaviour.

Violence against children in schools is common in
many LMIC and yet the evidence base for effective interventions is sparse. We are aware of only one trial: in primary schools in Uganda, a school-wide intervention involving staff, students and the school administration reduced past week physical violence against children by 42% (Devries et al. 2015). Importantly, benefits in the current study were found not only for teachers’ behaviour to the whole class but also to teachers’ behaviour to children at high risk for developing conduct problems. Increased positive attention and reduced negative attention to these children may have limited the escalating cycles of coercive behaviour between teachers and antisocial children (Patterson et al. 1992), and this is likely to be a key mechanism in the reductions in child conduct problems and increases in social skills found for these children (Baker-Henningham et al. 2012). In addition, due to the benefits to class-wide child behaviour, children at high risk for developing conduct disorder in intervention schools would be exposed to less aggression and increased appropriate behaviour from peers which may have also contributed to their improved behaviour at school and at home (Kellam et al. 1998). Benefits were also found to class-wide child interest and enthusiasm in learning activities and this increased participation is likely to lead to greater school bonding and increased learning, which are key predictors of improved behaviour (O’Donell et al. 1995). Benefits to teachers’ behaviours and to class-wide child behaviour were sustained at a 6-month follow-up. This trial is important to the global agenda on violence prevention in two main ways: (i) by reducing harsh punishment by teachers concurrently and at 6-month follow-up and (ii) by reducing conduct problems in children at high-risk of developing antisocial behaviour thus reducing future violence through early prevention. The sustained benefits of the intervention are promising as if teachers continue using the strategies, there are potential benefits to new cohorts of children. It will be important to determine if the benefits to teacher practices from interventions such as this are sustained over the long term and how frequently booster-training sessions may be required to ensure teachers continue to use the skills.

Benefits to teacher behaviour to the whole class were large compared to previous studies. For example, benefits from the IY teacher-training programme in the USA have been in the range 0.49–0.67 for ratings of harsh/critical practices and 0.51 for positive practices (Webster-Stratton et al. 2001, 2008), although large benefits were found for ratings of social-emotional teaching (ES = 0.96) and effective discipline (ES = 1.24) (Webster-Stratton et al. 2008). In the meta-analysis by Werner et al. (2016), training caregivers in early childhood settings led to medium effect sizes for caregiver-child interaction (ES = 0.44) and classroom quality (ES = 0.39). Benefits were likely larger in the current study due to the low level of initial training of the teachers thus widening the differences between the groups with intervention. For example, the largest effect sizes were found for the teacher behaviours that were less common in the Jamaican preschool context (teacher positives to the whole class and teacher provides opportunities to share and help). This explanation is also supported by the finding that in the IY teacher-training programme in the USA, effects sizes on critical behaviour for teachers more than 2 S.D. above the mean at baseline were 1.37 (compared to 0.49 for the entire sample) (Webster-Stratton et al. 2008). One study examined benefits of teacher training and consultation on teachers’ behaviour to children at high risk for aggression and found benefits to the amount of teacher feedback to

these high-risk children with effect sizes of 0.46–0.62 (The Metropolitan Area Child Study Research Group & Gorman-Smith, 2003), which are in a similar range to those found in this study.

This study also adds to the debate about the transportability of evidence-based child mental health interventions. Although we are aware of no studies empirically investigating the transportability of teacher interventions across cultures and contexts, meta-analytical studies of parenting interventions have mixed results with van Mourik et al. (2017) reporting increased effectiveness for ethnic minority families if interventions are adapted to fit the cultural context, whereas Gardner et al. (2016) found that interventions were at least as effective when transported across countries, suggesting that extensive adaption is not required. We chose to use the IY teacher-training programme as its collaborative nature makes it inherently adaptable and culturally sensitive and the IY programmes have been shown to be effective in multiple countries and with a range of ethnic groups (Menting et al. 2013). However, despite this in-built cultural flexibility, we found that an adapted version of the programme required significantly less in-class support than a minimally adapted version (4 sessions v. 21 sessions), to produce benefits of a similar magnitude to teachers’ classroom practices.

Teacher attendance and satisfaction was high with both versions of the programme required significantly less in-class support than a teacher only intervention (4 sessions v. 21 sessions), to produce benefits of a similar magnitude to teachers’ classroom practices. Teacher attendance and satisfaction was high with both the minimally adapted and significantly adapted version indicating that participant engagement was not the determining factor. The adaptations were aimed at promoting teacher understanding, confidence and ability to use the strategies in various situations across the school day and ensuring the skills and strategies were introduced in an ecologically valid way (i.e. in a way that was feasible in the Jamaican preschool context).

This increased the likelihood that teachers could successfully implement the strategies in the classroom without extensive in-class support and is important for implementation costs if the programme is to be widely disseminated. Other factors that need to be considered in transporting evidence-based interventions are the costs associated with the programme (both the upfront cost involved in purchasing the materials and any ongoing training costs) and its acceptability to policymakers and these factors are key for local adoption of the programme by the Ministry of Education and for ongoing sustainability.

It should be noted that caution needs to be exercised in comparing the results from this study to the results from the pilot study. The trials differed in several ways including different sampling criteria (the pilot study included two larger better resourced schools and three more typical schools), different lengths of observations (observations were conducted in the morning session only in the pilot study and for the whole day in the current study) and in the pilot study the teacher-training programme was supplemented with a structured curriculum unit on social–emotional skills.

The study has several strengths. The trial had high response rates and attrition was low. The randomisation led to balanced groups at baseline with no significant differences between the groups on any variable. All measurements involved independent observations which are less open to bias than teacher reports of their own behaviour, and observations were conducted by research assistants who were blind to the study design, hypothesis and group allocation. Furthermore, the trial included a 6-month follow-up showing that benefits were sustained after the end of the teacher-training period. There are also several limitations. Teachers were aware of their intervention status and it is possible that they behaved differently during observation. However, there is evidence that conducting observations over the whole day increases the reliability of data and minimises reactivity to being observed (Stoolmiller et al. 2000). In addition, community preschools in Jamaica have poor physical conditions including overcrowding, high noise levels, high child–teacher ratios and usually have several classrooms in a shared space and in this context, the observer is unobtrusive. Contamination between groups was minimised through the use of a cluster design; however, it is possible that some sharing occurred as schools were situated in a common geographical area, and over 20% of teachers in both groups were enrolled in teacher-training colleges; however, this would reduce the differences between the groups. The generalisability of the results may be limited by the fact that we excluded schools with fewer than 20 children per class and schools with fewer than three and more than four classrooms. However, as the intervention is delivered to all teachers within the school, we anticipate that teachers in smaller and larger schools would also benefit.

Conclusions

We found large, significant benefits to teachers’ behaviour and class-wide child behaviour from an intervention providing teachers with training in classroom behaviour management and in how to promote children’s social–emotional competence. These benefits were assessed by independent, masked observers and sustained at 6-month follow-up. The intervention also led to significant benefits to the behaviour of children at high risk for developing conduct problems at home and at school (see Baker-Henningham et al. 2012). Furthermore, we report that making substantial adaptations to an evidence-based programme to ensure contextual fit reduced the amount of individual support teachers need in order to use the skills...
effectively. We used the IY teacher-training programme and the content was relevant and appropriate to the Jamaican context and we believe that the majority of the strategies introduced through the programme are applicable across different cultures and contexts. However, we also found that adaptations to the materials and methods used improved the cultural and contextual fit and we tentatively conclude that although the strategies are generally relevant and applicable, how they are operationalised in practice is likely to differ across different cultures, contexts and situations. The intervention was implemented through the existing educational services and involved training existing staff and hence should be feasible and sustainable at scale. Training teachers has the advantage that multiple high-risk children can be helped and teachers can continue benefiting new cohorts of children over time. The findings have important implications for child mental health in low-resource settings and show that teacher-training programmes are an important component of initiatives to prevent violence against children, promote child well-being and prevent child mental health problems in LMIC.

Acknowledgements

This work was supported by The Wellcome Trust (grant numbers 080534/Z/06/Z and 094307/Z/10/Z). The funder had no role in the conduct of the study, the interpretation of the data or the decision to submit for publication. We thank Yakeisha Townsend for assisting with the intervention; the staff, parents and children of the 24 community preschools for their participation and the research assistants for data collection.

Ethical Standards

The authors assert that all procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees on human experimentation and with the Helsinki Declaration of 1975, as revised in 2008.
