METHOD TO PRODUCE URANIUM SILICIDES

STATEMENT REGARDING GOVERNMENT RIGHTS

[0001] This invention was made with government support under Contract No. DE-NE0008222 awarded by the Department of Energy. The U.S. Government has certain rights in this invention.

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0002] The present invention relates to methods of manufacturing uranium silicides for use as nuclear fuel and, more particularly, to a process for producing uranium silicides using uranium carbide as an intermediate.

2. Description of the Prior Art

[0003] The preparation of commercial nuclear fuels mainly has been by processes which use enriched and depleted uranium (i.e., enriched or depleted in the uranium-235 isotope as compared to the uranium-235 content of naturally occurring uranium ore) feed as UF₆. The enriched UF₆ is converted to UO₂ by processes selected to give the ceramic sinterability needed for the preparation of nuclear fuel pellets.

[0004] Early patents issued to Reese et al., U.S. Pat. No. 3,168,369, filed in 1961, and to Blundell et al., U.S. Pat. No. 3,235,327, filed in 1962, described all the basic reactions and general technology required to make uranium dioxide nuclear fuel for nuclear reactors from uranium hexafluoride.

[0005] Numerous U.S. patents have been subsequently issued directed towards processes for the conversion of UF₆ to uranium oxides. See, for example, U.S. Pat. No. 4,830,841 and the U.S. patents listed therein, which describe procedures for converting UF₆ to uranium dioxide in furnaces, rotary kilns, fluidized beds and the like.

[0006] Other U.S. patents disclose single-step processes for producing nuclear reactor fuel, such as U.S. Pat. No. 4,397,824 and U.S. Pat. No. 5,875,385. An exemplary single-step process for producing solid uranium oxide powder is disclosed in U.S. Pat. No. 5,752,158, which describes a single-step Modified Direct Route (MDR) process for producing solid uranium oxide powder and gaseous HF from UF₆ by bringing together two gaseous reactant streams, one of the streams comprising UF₆ optionally admixed with oxygen as O₂, and the second reactant stream comprising a mixture of hydrogen as H₂ or as a hydrogen-containing compound and oxygen as an oxygen-containing compound. The gaseous reactant streams are brought together at a temperature and composition such that the UF₆ is converted rapidly by flame reaction into readily separable solid uranium oxide and a gaseous HF product.

[0007] Additional single-step dry processes for obtaining uranium dioxide powder (i.e., by direct reduction of UF₆ into UO₂) which include the Intermediate Dry Route process have been widely used and are described in, for example, U.S. Pat. No. 4,889,663 and U.S. Pat. No. 4,397,824. The powders obtained by the dry conversion process, including water vapor hydrolysis followed by pyrohydrolysis of the uranyl fluoride UO₂F₄, obtained, have the advantage of being readily sinterable. The powder produced is very active but hard to handle and produces very weak green pellets. Handling therefore is delicate and rejects are numerous if special care is not exercised.

[0008] U.S. Pat. No. 6,656,391 discloses the use of a wet ammonium diuranate process (ADU) to produce both UO₂/F and UF₆, from both uranyl nitrate hexahydrate (UNH) and UF₆. In particular, the UO₂/F is that produced from this process then is processed in a calciner to produce UO₂. The ADU process produces a stable but only moderately active (i.e., only achieves a final pellet density of about 97.5% on a consistent basis) UO₂ powder.

[0009] Uranium silicide fuels, such as U₁₂Si₃, are conventionally produced by mixing uranium and silicon metals together and melting them at temperatures greater than 1665° C. UF₆ is the most common commercial uranium feedstock. When making U₁₂Si₃, UF₆ must first be converted into a uranium metal in a multi-step process which is costly and difficult for large scale manufacturing.

[0010] For example, one high temperature process, UF₆+H₂→2HF+UF₄, generates a very corrosive HF atmosphere. Isolating the uranium in a procedure such as UF₆+2Mg→U+2MgF₂, relies on a high temperature process with a uranium metal product. The resulting uranium metal is mixed with silicon metal to make U₁₂Si₃, represented by 3U+2Si→U₁₂Si₃, at temperatures greater than 1652° C. Uranium metal is very dense. Only small quantities of the U metal may be used in any bath because larger quantities can start a uranium fission process. Each of these steps therefore has criticality issues for large scale manufacturing and batch processing.

[0011] A safer, more cost effective method is desired.

SUMMARY OF THE INVENTION

[0012] The method described herein addresses the problem associated with the use of uranium and silicon metals in the production of uranium silicides.

[0013] In various aspects, a method is described herein that comprises forming uranium dioxide, reacting uranium dioxide with a source of carbon to produce uranium carbide, and, reacting uranium carbide with a silicon based reactant comprised of a silane, a silicon halide, a siloxane, and combinations thereof, in the presence of excess hydrogen to produce a uranium silicide.

[0014] Uranium dioxide may be formed by a process selected from the group consisting of an ammonium uranyl carbonate process, an ammonium diuranate process, and an integrated dry route process, or any other suitable known process.

[0015] The uranium dioxide may be formed from uranium fluoride. In various aspects, the uranium fluoride may be selected from uranium hexafluoride (UF₆), uranyl fluoride (UO₂F₂) and uranium tetrafluoride (UF₄).

[0016] The method described herein, or one or more steps of the method, in various aspects, may be carried out in a rotary kiln. The step of the method for forming the uranium silicides may be carried out at a temperature not far beyond the reported decomposition temperature of SiH₄, for example a temperature greater than about 623 K to 673 K (about 350-400° C.). The temperature for the uranium
silicide forming step may, however, range from between about 500 K to 800 K (about 227° C. to 527° C.), and preferably may be between about 500 K and 700 K (about 227° C. and 427° C.). The preceding steps of the method may be carried out at temperatures below the melting point of the reactants, and may, for example, be carried out generally at temperatures below the melting point of the targeted stoichiometry of the targeted uranium silicide.

**0017** The targeted uranium silicide may be $\text{U}_2\text{Si}_3$. However, the ratio of uranium to silicon in the uranium silicon product may be varied by varying the ratio of feed compounds used to form uranium silicide, uranium carbide, and one of silicon hydride and silicon halide.

**0018** A homogenization step at high temperatures may be required once the formation of the uranium silicide reaction has been completed to reduce the content of phases with varied stoichiometries compared to the target $\text{U}_2\text{Si}_3$. This can be carried out at temperatures up to the target material’s melting point (e.g., 1665° C. for $\text{U}_2\text{Si}_3$).

**BRIEF DESCRIPTION OF THE DRAWINGS**

**0019** The characteristics and advantages of the present disclosure may be better understood by reference to the accompanying figure, which provides a graph showing the Gibbs free energy (eV) values of several reactants (H, Cl, F, and Br) over a range of temperatures from 0 to 2000 K.

**DESCRIPTION OF THE PREFERRED EMBODIMENTS**

**0020** As used herein, the singular form of “a”, “an”, and “the” include the plural references unless the context clearly dictates otherwise.

**0021** In the present application, including the claims, other than where otherwise indicated, all numbers expressing quantities, values or characteristics are to be understood as being modified in all instances by the term “about.” Thus, numbers may be read as if preceded by the word “about” even though the term “about” may not expressly appear with the number. Accordingly, unless indicated to the contrary, any numerical parameters set forth in the following description may vary depending on the desired properties one seeks to obtain in the compositions and methods according to the present disclosure. At the very least, and not as an attempt to limit the application of the doctrine of equivalents to the scope of the claims, each numerical parameter described in the present description should at least be construed in light of the number of reported significant digits and by applying ordinary rounding techniques.

**0022** Any numerical range recited herein is intended to include all sub-ranges subsumed therein. For example, a range of “1 to 10” is intended to include all sub-ranges between (and including) the recited minimum value of 1 and the recited maximum value of 10, that is, having a minimum value equal to or greater than 1 and a maximum value of equal to or less than 10.

**0023** The term “rotary kiln” or alternatively, “calciner,” means a rotating tubular pyrohydrolysis oven, for example, one provided with heater means, powder feed means at an entry end and injector means near the reaction product exit for injecting, for example, a countercurrent flow of one or more of steam, gaseous $\text{H}_2\text{O}$ and $\text{H}_2$ as generally described in U.S. Pat. No. 6,136,285, or other commercially available equivalent ovens.

**0024** The method described herein may be characterized as reacting uranium dioxide with carbon to produce uranium carbide, and, reacting the uranium carbide with a silicon based reactant comprised of a silane, a silicon halide, a siloxane, and combinations thereof, and excess hydrogen to produce uranium silicide.

**0025** The method may in various aspects be characterized as forming uranium dioxide, reacting uranium dioxide with carbon from any suitable carbon source, such as graphite or carbon black, to produce uranium carbide, and, reacting the uranium carbide with a silicon based reactant in a linear, branched, or cyclic configuration. The silicon based reactant may be selected from a silane (e.g., $\text{SiH}_x$, $\text{Si}_2\text{H}_x$, $\text{Si}_3\text{H}_x$, $\text{Si}_4\text{H}_x$, or $\text{Si}_n\text{H}_x$), a silicon halide (e.g., $\text{SiF}_x$, $\text{SiH}_x\text{F}_x$, $\text{Si}_2\text{H}_x\text{F}_x$, $\text{Si}_3\text{H}_x\text{Cl}_x$, $\text{Si}_4\text{H}_x\text{B}_x$, $\text{Si}_4\text{H}_x\text{I}_x$, or $\text{Si}_n\text{H}_x\text{Cl}_x$, and the like), or a siloxane (e.g., $\text{Si}_2\text{O}$) in the presence of excess hydrogen ($\text{H}_2$) to produce uranium silicide.

In various aspects, the silicon based reactant may have the general formula $\text{Si}_n\text{X}_{2n+2}$, where $n$ is from 1 to 6 and $X$ is selected from the group consisting of hydrogen, halides, and combinations thereof. In other aspects, the silicon based reactant may be in a cyclic configuration having fewer than $2n+2$ $X$ molecules.

**0026** An exemplary representation of the method may be shown as:

$$\text{UO}_2 + 3\text{C} \rightarrow \text{UC} + 2\text{CO}$$

Uranium carbide is reacted with a stoichiometric amount of a silicide, in an exemplary reaction that proceeds as follows:

$$\text{UC} + 2\text{Si} \rightarrow \text{UC}_2 + 2\text{Si}$$

The uranium carbide is reacted with a stoichiometric amount of a silicide, in an exemplary reaction that proceeds as follows:

$$\text{UC} + 2\text{Si} \rightarrow \text{UC}_2 + 2\text{Si}$$

The conversion of uranium dioxide to uranium carbide may proceed as follows:

$$\text{UO}_2 + 3\text{C} \rightarrow \text{UC} + 2\text{CO}$$

The uranium carbide is reacted with a stoichiometric amount of a silicide, in an exemplary reaction that proceeds as follows:

$$3\text{UC} + 2\text{SiX}_x \rightarrow \text{UC}_2 + 3\text{SiX}_x$$

wherein $X$ is preferably $\text{H}$, such that the reaction may be represented as follows:

$$3\text{UC} + 2\text{SiH}_x \rightarrow \text{UC}_2 + 3\text{SiH}_x$$

X may also be a halide selected from the group consisting of F, Cl, B, and I, or a mixture of H and halide. If $X$ is a halide, the reaction has been thermodynamically determined to be more difficult due to the high Gibbs free energy in the halide systems, as shown in the attached figure.

**0027** Suitable known methods for producing uranium oxides include, for example, ammonium uranyl carbonate (AUC), ammonium diuranate (ADU), and integrated dry route (IDR) processes. Those skilled in the art will appreciate that any source of or method of producing uranium dioxide will suffice.

**0028** An exemplary ammonium uranyl carbonate (AUC) process may, in various aspects, be a two-step process that proceeds as follows:

$$\text{UF}_6 + 5\text{H}_2\text{O} + 10\text{NH}_3 + 3\text{CO}_2 \rightarrow (\text{NH}_4)_2\text{U}_2\text{(CO}_3\text{)}_3+$$

$$6\text{NH}_4\text{F}$$

$$(\text{NH}_4)_2\text{U}_2\text{(CO}_3\text{)}_3+\text{H}_2+\text{UO}_2+4\text{NH}_3+3\text{CO}_2+3\text{H}_2\text{O}.$$
composition represented by \((\text{NH}_4)_4(\text{UO}_2(\text{CO}_3)_3)\). The \(\text{UO}_2\) conversion is characterized by the formation of discrete particles of 40-300 \(\mu\)m in size, which permits direct pelletizing.

[0029] An exemplary ammonium diuranate (ADU) process may vary in various aspects proceed by reacting \(\text{UF}_6\) with water to form a uranium fluoride solution or uranyl nitrate solution with ammonium hydroxide solution to produce an ADU precipitate. Following calcination of the ADU precipitate in nitrogen and reduction with the steam-hydrogen gas mixture, reaction products are converted to \(\text{UO}_2\) powders. The reaction may generally be represented as follows:

\[
\text{UF}_6 + 2\text{H}_2\text{O} \rightarrow \text{UO}_2\text{F}_2 + 4\text{HF},
\]

(at about 120°F (about 48.9°C).)

\[
\text{UO}_2\text{F}_2 + 2\text{NH}_2\text{OH} \rightarrow \text{UO}_2(\text{NH})_2 + 2\text{HF}
\]

(at about 70°F (about 21°C).)

\[
\text{UO}_2(\text{NH})_2 + 2\text{H}_2\text{O} \rightarrow \text{UO}_2(\text{NH})_2\text{H}_2\text{O}
\]

(at about 1100°F (about 593°C).)

[0030] An integrated dry route (IDR) process changes \(\text{UF}_6\) into a ceramic grade uranium dioxide (\(\text{UO}_2\)) powder, typically in a single stage, by mixing steam and hydrogen in a kiln, such as, for example, a rotary kiln, to produce \(\text{UO}_2\) and HF gas. In an exemplary process, uranium hexahydride gas is blown into a kiln, or calciner, and mixed with steam and excess hydrogen at 1100°F (about 593°C) at atmospheric pressure. The reaction may be represented generally as follows:

\[
\text{UF}_6 + \text{H}_2 + \text{H}_2\text{O} \rightarrow \text{UO}_2 + 6\text{HF}
\]

Excess hydrogen remaining after the reaction is burned off and HF gas is captured as an HF solution.

[0031] The uranium dioxide produced in any of these or other reactions is in a powder form. The \(\text{UO}_2\) powder may be combined in a calciner, rotary kiln, with solid carbon in a hydrogen atmosphere to create a reducing atmosphere. The carbon may be from any suitable carbon source, such as, for example, graphite, carbon black, or other suitable sources of carbon. The uranium dioxide and carbon react to form uranium carbide and either carbon monoxide or carbon dioxide, or combinations of carbon monoxide and carbon dioxide. Excess hydrogen and the carbon monoxide and/or carbon dioxide reaction products may be in gaseous form and are flared off or removed by other suitable means. The uranium carbide reaction product is a solid.

[0035] An advantage of uranium carbide is that uranium is highly covolatile, with an effective valence of close to zero. Conversion of uranium carbide, for example, to \(\text{U}_2\text{Si}_2\), involves replacing carbon with silicon. Silicon can be introduced in several ways, such as by reacting uranium carbide powder in a calciner with, for example, excess of silane gas (\(\text{SiH}_4\)) in the presence of excess hydrogen gas (\(\text{H}_2\)). The powder and gases would be rotated in the calciner at a temperature between about 500 to 800 K (about 227° C. to 527° C), and preferably between 500 and 700 K (about 227° C. and 427° C.) at atmospheric pressure to yield \(\text{U}_2\text{Si}_2\) and methane gas, which may be represented as

\[
3\text{UC}_2 + 2\text{SiH}_4 + 2\text{H}_2 \rightarrow \text{U}_2\text{Si}_2 + 3\text{CH}_4
\]

The excess silane and hydrogen drive the reaction to \(\text{U}_2\text{Si}_2\). The methane reaction product can be off-gassed, burned off, or removed by any suitable means.

[0036] In various aspects, uranium silicide compounds other than \(\text{U}_2\text{Si}_2\) may be formed by changing the rate of addition of \(\text{SiH}_4\) and \(\text{H}_2\) gases to change the ratio of reactants. Examples of other uranium silicides include \(\text{USi}_2\), \(\text{U}_2\text{Si}, \text{USi},\) and \(\text{U}_3\text{Si}_2\). Practice, a combination of the uranium silicides would be produced. Those skilled in the art will appreciate that reactant ratio manipulation can drive the reaction to produce more of a desired product.

[0037] Several reaction schemes were studied thermodynamically using silane and several silicon halides. The silane reaction, \(3\text{UC}_2 + 2\text{SiH}_4 + 2\text{H}_2\), has a negative Gibbs free energy, as shown by the diamond in the graph of the attached figure. The silicon halide reactions, represented generally by \(3\text{UC}_2 + 2\text{SiX}_4 \rightarrow \text{U}_2\text{Si}_2 + 2\text{CX}_4\), where \(X\) is selected from the group consisting of \(\text{Br}, \text{Cl}, \text{F}\), and \(I\), shown in the graph of the figure by an X (Br), square (CO), and a triangle (F), have positive Gibbs free energies, so are less desirable reaction schemes than the negative free energy for silane. Iodine is not shown, but would be expected to also have a positive free energy, falling above bromine on the graph.

[0038] Although the silane reaction, wherein \(X\) in the general formula \(\text{Si} \times \text{X} + 2\text{H}_2 + 2\text{H}_2\), is preferred, the silicon halide reactions, wherein \(X\) may be a halide or both \(H\) and a halide, may be more useful in removing traces of residual carbon from the \(\text{U}_2\text{Si}_2\), and other uranium silicide reaction products. Reactions using silicon halides would also be carried out in a rotary kiln within the same temperature range and at the same pressure as the reaction using silane. A homogenization step using silicon halides may be carried out after the uranium silicide is formed to remove traces of residual carbon. This can be carried out at temperatures up to the target uranium silicide material’s melting point.

[0039] The method described herein is much more cost effective than the conventional method that uses silicon metal to produce \(\text{U}_2\text{Si}_2\), and can be carried out in equipment that can operate at temperatures greater than 500°C, but lower than the melting point of the target stoichiometry of the target uranium silicide, for example, \(\text{U}_2\text{Si}_2, \text{USi}_2, \text{U}_2\text{Si}, \text{USi},\) or combinations thereof, thus significantly improving safety by eliminating the need to handle corrosive molten materials.

[0040] All patents, patent applications, publications, or other disclosure material mentioned herein, are hereby incorporated by reference in their entirety as if each individual reference was expressly incorporated by reference respectively. All references, and any material, or portion thereof, that are said to be incorporated by reference herein are incorporated herein only to the extent that the incorporated material does not conflict with existing definitions, statements, or other disclosure material set forth in this disclosure. As such, and to the extent necessary, the disclosure as set forth herein supersedes any conflicting material incorporated herein by reference and the disclosure expressly set forth in the present application controls.

[0041] The present invention has been described with reference to various exemplary and illustrative embodiments. The embodiments described herein are understood as providing illustrative features of varying detail of various embodiments of the disclosed invention; and therefore, unless otherwise specified, it is to be understood that, to the extent possible, one or more features, elements, components, constituents, ingredients, structures, modules, and/or aspects of the disclosed embodiments may be combined, separated, interchanged, and/or rearranged with or relative to one or
The method recited in claim 1 wherein the ratio of uranium to silicon in the uranium silicide product is varied by the ratio of feed compounds used to form one or more of uranium dioxide, uranium carbide, and the silicon based reactant.

11. The method recited in claim 1 wherein the process is carried out in a rotary kiln.

12. The method recited in claim 1 wherein each step is carried out at temperatures below the melting point of reactants contributing to the targeted stoichiometry of uranium silicide.

13. The method recited in claim 1 wherein the step of forming the uranium silicide is carried out at temperatures between 500 and 800 K.

14. The method recited in claim 1 further comprising homogenizing the uranium silicide product at a temperature above the temperature at which the formation of the uranium silicide is carried out and below the melting temperature of the uranium silicide.

15. A method for producing a uranium silicide nuclear fuel comprising a reaction represented by:

\[ \text{UF}_6 + 3 \text{H}_2 \rightarrow \text{UO}_2 + 6 \text{H}_2 \]

(1)

and

\[ \text{UO}_2 + 2 \text{C} \rightarrow \text{UC} + \text{CO}_2 \]

(2) one or both of

\[ \text{UC} + \text{Si} \rightarrow \text{UC} + \text{Si}_2 \]

(3)

wherein X is selected from the group consisting of H, Cl, F, Br, and I and combinations thereof.

16. The method recited in claim 15 wherein the process is carried out in a rotary kiln.

17. The method recited in claim 15 wherein step (3) is carried out at temperatures between 500 and 800 K.

18. The method recited in claim 15 wherein, following the third reaction step, residual carbon is removed by reacting the residual carbon with a silicon halide and excess halide.

19. The method recited in claim 16 wherein the halide is selected from the group consisting of fluoride, chloride, bromide, iodide, and combinations thereof.

20. The method recited in claim 15 further comprising homogenizing the uranium silicide product at a temperature below the melting temperature of the uranium silicide product.
