The effect of uniform electric field on low temperature (T=0 K) multisubband electron mobility $\mu_i$ is analyzed by considering a barrier delta-doped Ga$_{0.5}$In$_{0.5}$P/GaAs coupled double quantum well structure. We consider ionized impurity scattering and interface roughness (IR) scattering. The screening of the scattering potentials is obtained by adopting the random phase approximation. Starting with a double-subband occupied system we have studied the changes in the intersubband and intersubband scattering processes by varying the electric field $F$ and highlight the influence of $F$ on the intersubband effects which yields interesting results on $\mu_i$. At a certain electric field, the system undergoes a transition from double subband to single subband occupancy leading to a large enhancement in mobility due to the suppression of the intersubband interactions. We show that by reversing the electric field a large change in mobility is obtained due to the asymmetric nature of the IR scattering potential. It is also gratifying to show that by varying the electric field the relative dominance of different scattering mechanisms on subband mobility changes through the intersubband interaction. © 2010 American Institute of Physics. I. INTRODUCTION

In recent years many attempts have been made to utilize electric field effects on coupled quantum well structures in developing electronic and optoelectronic devices. Novel functional quantum well devices have been fabricated by using the concept of resonant tunneling of electrons perpendicular to the interface planes.1–3 Significant effort also been given utilizing coupled quantum wells or short period superlattices as quantum cascade lasers which have been shown to be reliable, compact, and high power optical sources in the midinfrared and terahertz frequency range.4–6 The application of an electric field, perpendicular to the interface plane, changes the potential profile of a quantum well structure and thereby changes the subband energy levels. The subband wave function distributions also are amended thus affecting electron transport parallel to the interface plane. Basu and Raychaudhury7 have studied the effect of electric field applied perpendicular to the layer plane in In$_{0.53}$Ga$_{0.47}$As/InP single quantum well structures and showed that increase in the electric field causes an increase in the scattering rate induced by the alloy disorder scattering. Lima et al.8 have calculated the low temperature electron mobility in n-AlGaAs/GaAs/AlGaAs single asymmetric quantum wells in the presence of a uniform electric field perpendicular to the interface plane. They have shown that by changing the longitudinal electric field the electron wave function can be dislocated so that one can enhances the two-dimensional (2D) electron mobility. In the above work the electron mobility was studied by considering single quantum well structures in which only the lowest subband is occupied. Attempts have also been made to study carrier mobility in different quantum well structures by carrying out Monte Carlo simulation.9–12 However, to the best of our knowledge, the study of the effect of electric field on multisubband electron mobility, which very much relies on the intersubband interactions, has not previously been reported.

A double quantum well structure13 exhibits the phenomenon of tunneling coupling in addition to quantum confinement effects. Double quantum well structures have been widely used not only to investigate the interesting physical phenomena of coupled 2D electron gas (2DEG) systems but also to fabricate novel electronic and optoelectronic devices.14–16 In a double quantum well structure the subband electron wave functions of the individual wells overlap through a thin central barrier exhibiting splitting in the subband energy levels. By changing the well width, barrier width and carrier concentration, the subband energy levels change and hence for a certain set of values of the material parameters, the system undergoes transition from single subband occupancy to double subband occupancy. The electron transport in such multisubband occupied systems has been shown to be influenced by intersubband interactions.17–22 In a recent paper22 we studied the effect of intersubband interaction on the subband mobility of a coupled GaInP/GaAs double quantum well structure. We showed that the intersubband interaction not only controls the effect of roughness of different interfaces but also exhibits interesting results on the well width up to which the interface roughness (IR) dominates in a double quantum well structure.

In the present paper, we analyze the effect of the electric field perpendicular to the interface plane on the electron transport in a coupled double channel multisubband quantum well system. We consider a lattice matched GaInP/GaAs symmetric double quantum well structure. The low temperature electron mobility is assumed to be due to ionized impurity scattering and IR scattering. The screened scattering po-
tentials are obtained by using the random phase approximation (RPA) formalism. We have considered a double subband occupied system and studied the effect of dislocation of the subband wave functions on the intrasubband and intersubband scattering rate matrix elements of different scattering mechanisms by changing the field strength. We show that the mobility increases with the electric field mainly due to the change in the intersubband scattering rate matrix elements. For a certain value of the electric field there is a cross over from double subband to single subband occupancy leading to a large enhancement in the mobility. This enhancement in mobility is due to the suppression of the intersubband effects. By reversing the electric field a large change in mobility occurs due to the asymmetric nature of the IR scattering potential. Normally in quantum wells having narrow widths, the mobility is dominated by IR scattering. We show here that in the presence of an electric field the dominance of IR scattering on mobility persists in quantum wells of larger well widths. It will be of interest to compare our results with the experimental results when such are available.

II. THEORY

We consider a symmetric GaAs/In$_{0.33}$Ga$_{0.67}$P double quantum well structure with a thin central barrier (InGaP) of width $b$ ($-b/2 \leq z \leq b/2$). The adjacent wells are of width $w$. The outer barriers are delta-doped with Si at a distance $s$ from the adjacent wells. The doping layer width and doping concentration are $d$ and $N_0$, respectively. The barrier height $V_b$ at the interfaces is taken as the conduction band offset of the InGaP layer and the GaAs layer. Two symmetric triangular-like potential wells in the GaAs layers near the interfaces with the outer barriers are formed due to Coulomb interaction between the ionized impurities in the barrier and the diffused electrons in the wells and also alignment of the Fermi level ($E_F$) throughout the system. The electrons are thus confined to two narrow strips forming two sheets of 2DEG (Ref. 17) coupled through a thin central barrier.

The electron subband wave functions and the energy eigenvalues for the 2D system can be obtained as

$$\psi_{ik}(z) = \frac{e^{ikz}}{A}$$

and

$$E_{ik} = E_i + \frac{\hbar^2 k^2}{2m^*}$$

where $\tilde{\rho}$ is the 2D position vector parallel to the interface plane (xy-plane) and $k$ is the corresponding wave vector.

A is the area of the sample perpendicular to the z-axis and $m^*$ the electron effective mass. $E_i$ is the subband energy level, $i=0,1,2,3\ldots$ being the subband index. In the presence of a longitudinal electric field, parallel to the z-direction, the envelope function $\psi_i(z)$ satisfies the one-dimensional Schrödinger equation,

$$-\frac{\hbar^2}{2m^*} \frac{d^2}{dz^2} + V(z) + eFz \psi_i(z) = E_i \psi_i(z),$$

where $F$ is the electric field strength. The Hartree potential $V(z)$ which causes band bending due to the electrostatic interaction of the electrons and the ionized impurities, is obtained by solving Poisson’s equation

$$\frac{d^2 V}{d z^2} = \frac{4\pi e^2}{\varepsilon_o} [n_D(z) - n(z)],$$

where $\varepsilon_o$ is the dielectric constant of the layer, $n_D(z)$ and $n(z)$ are the impurity and electron concentration distributions, respectively,

$$n_D(z) = N_0 \ b/2 + w + s < |z| < b/2 + w + s + d$$

$$= 0 \quad \text{otherwise}$$

$$n(z) = \sum_i n_i |\psi_i(z)|^2 - \infty < z < + \infty,$$

where $n_i$ is the number of electrons per unit area in the $i$th subband

$$n_i = \left( \frac{m^*k_BT}{\pi\hbar^2} \right) \ln [1 + e^{(E_F - E_i)/k_BT}],$$

where $E_F$ is the Fermi energy. At $T=0$, the surface electron density $N = 2N_0/C$ is related to the Fermi energy through $n_i$ as

$$N = \sum_{i=1}^{p} n_i \theta(E_F - E_i),$$

where $p$ is the number of filled levels, $\theta$ is the heaviside step function.

We obtain an expression for $V(z)$ by solving the Poisson’s equation with the use of a trial wave function and adopting the variational formalism. We use electrostatic boundary conditions at the interfaces and the condition that the electrostatic potential remains constant ($V_b/e$) and the electric field vanishes at the extremes of the structure. We also incorporate the conduction band discontinuity at the interfaces. We obtain an analytical expression for the potential profile as a function of the electric field and calculate the transmission coefficient through the potential profile by adopting the multistep potential approximation to numerically calculate the bound subband energy levels $E_i$, wave functions $\psi_i$ and subband electron density $n_i$.

The electron mobility $\mu$ can be written as $1/\mu = \Sigma_i 1/\mu^i$, where $s$ denotes the different scattering mechanisms. We consider that the low temperature mobility is governed by IR scattering and ionized impurity scattering. $\mu^s$ is defined by the subband transport mobility $\mu^i_s$ as

$$\mu^i_s = \frac{\Sigma n_i \mu^i_s}{\Sigma n_i}.$$  

Further, the subband transport mobility $\mu^i_s$ and subband transport life time $\tau^i_s$ of an electron in the $i$th subband is given by
\[
\mu_i^*(e) = \frac{e}{m^*} \tau_i^*(e). \tag{9}
\]

At \(T=0\) K the electrons on the Fermi surface contribute to electron transport. Therefore we have \(\tau_i^*(E_{F_i})\), where \(E_{F_i} = E_{F_i} - E_i\) is the Fermi level in the \(i\)th subband. In general, for a multisubband system the expressions for \(\mu_i^*\) are difficult to interpret as they are comprised of intrasubband and intersubband scattering processes in a mixed way. However, for a single occupied subband \((i=0)\), one can obtain \(\tau_0^* = \tau_0^0\).

The intrasubband scattering rate matrix element \(B_{ii}^*\) is given by the scattering matrix elements \(V_{ii}^*(q)\) as

\[
B_{ii}^* = \frac{m}{\pi \hbar^3} \int_0^\pi d\theta (1 - \cos \theta) |V_{ii}^*(q_0)|^2, \tag{11}
\]

where \(q_0 = 2k_{F_i} \sin \theta / 2\). Similarly the expressions for \(\tau_i^*\) for a system with double occupied subbands can be obtained by taking \(i=0\) and 1 as \(\tau_0^* = \tau_0^0\) and \(\tau_1^* = \tau_1^1\),

\[
\frac{1}{\tau_0^0} = (B_{00}^0 + C_{01}^0)(B_{11}^0 + C_{10}^0) - D_{00}^0 D_{11}^0,
\]

where \(C_{ij}^\pm\) and \(D_{ij}^\pm\) are intersubband scattering rate matrix elements.

\[
B_{ii}^* = \frac{m}{\pi \hbar^3} \int_0^\pi d\theta |V_{ii}^*(q)|^2, \tag{14}
\]

\[
D_{ij}^* = \frac{m}{\pi \hbar^3} \int_0^\pi d\theta |V_{ij}^*(q)|^2. \tag{15}
\]

Here \(q_{ij} = (k_{F_i} + k_{F_j}^2 - 2k_{F_i}k_{F_j} \cos \theta)^{1/2}\). For screened ionized impurity scattering, \(V_{ij}^*\) can be written as \(\mu_{ij}^*\),

\[
|V_{ij}^{imp}(q)|^2 = \frac{4 \pi^2 e^4 N_0}{\varepsilon_{0q}^2} \times \left[ \int_{-(b/2+w+s)}^{-(b/2+w+s+d)} dZ \sum_{i',j'} \varepsilon_{ij,i',j'}^1(q) P_{i',j'}(q,Z) \right]^2 + \int_{(b/2+w+s+d)}^{(b/2+w+s)} dZ \sum_{i',j'} \varepsilon_{ij,i',j'}^1(q) P_{i',j'}(q,Z), \tag{16}
\]

where \(P_{i',j'}(q,Z) = \int_{-\infty}^{\infty} dz \psi_{ij}(z) \psi_{ij}(z) e^{-q|z-Z|}\),

\[
\sum_{i',j'} \varepsilon_{ij,i',j'}^1(q) = \delta_{ii'} \delta_{jj'} + (q_z/q) f_{i',j'}(q) \chi_{i',j'}^0(q), \tag{18}
\]

where \(q_z = 2m_e^2 / \varepsilon_0 \hbar^2\) and \(f\) is the Coulomb form factor and \(\chi_{i',j'}^0(q)\) is the static electron density-density correlation function without electron-electron interaction. For screened IR scattering potential, we consider an expression appropriate for a finite well of height \(V_0\) (Refs. 26–28)

\[
|V_{ij}^{IR}(q)|^2 = \sum_i \sum_{i'=j'} \sum_{i'=j'} \frac{q}{q_{ij}} \times \left[ \sum_{i',j'} \varepsilon_{ij,i',j'}^1(q) \chi_{ij}(z) \chi_{i',j'}(z) \right]^2, \tag{19}
\]

since the corresponding equation for an infinite well, given by Prange and Nee, \(29\) has been shown to be not very accurate. \(27\) In the above equation, \(\Delta_j\) is the mean height and \(\Lambda_j\) is the correlation length of the roughness of the \(j\)th interface at \(z = z_j\). We consider the scattering of impurities from the two \(\delta\)-doped layers in the outer barriers. In the case of IR scattering, basing upon experimental evidence, the interfaces lying on the substrate side of the wells are assumed to be significant. \(30–32\) We thus consider the scattering from the first \((I_1)\) and third \((I_3)\) interfaces, say, from left of the structure, i.e., \(z_1 = -(b/2+w)\) and \(z_3 = b/2\). We assume that the interfaces are equally rough.

**III. RESULTS AND DISCUSSION**

We calculate the subband electron mobility \(\mu_i\) in a GaInP/GaAs double quantum well structure by changing the strength of the uniform applied electric field \(F\) (in kV/cm). We consider a typical case in which the two lowest subbands are occupied by taking well width \(w = 100\) Å. The other parameters of the structure are: \(b = 20\) Å, \(s = 80\) Å, \(d = 20\) Å, \(N_0 = 1 \times 10^{18}\) cm\(^{-3}\), and \(N_s = 4 \times 10^{11}\) cm\(^{-2}\). The effective mass of the electron \(m^*\) (in \(m_0\)) and the static dielectric constant \(\varepsilon_0\) for GaAs/GaInP are 0.067/0.092 and 13.18/11.8, respectively. The barrier height \(V_b = 130\) meV and the IR parameters \(\Delta = 5.67\) Å and \(\Lambda = 140\) Å. \(33\) Our aim is to analyze the sum over \(i'\) and \(j'\) runs over all the subband levels of the system. Within the RPA the dielectric function matrix can be written as

FIG. 1. Subband energy levels \(E_0\) and \(E_1\) and Fermi energy level \(E_F\) in meV as a function of electric field \(F\) in kV/cm along the negative z-axis. At \(|F| = 10\) kV/cm transition from double subband occupancy to single subband occupancy is exhibited.
the effect of the electric field on the intra- and intersubband scattering rates mediated by intersubband interactions.

In Fig. 1, we plot the results of \( E_0 \), \( E_1 \), and \( E_F \) (meV) as a function of the electric field \( F \) (kV/cm) perpendicular to the interface plane and directed along the negative \( z \)-axis. A change from double-to-single subband occupancy occurs as \( F \) increases from 9 to 10 kV/cm. By reverting the field \( F \) along \( x \)-axis, the magnitudes of \( E_0 \), \( E_1 \), and \( E_F \) change. However, the subband Fermi energy \( E_F = (E_F - E_i) \) (meV) remains invariant because of the symmetric nature of the potential profile of the structure at \( F = 0 \) (Fig. 2). In Figs. 2–4, we plot \( V(z) \), \( E_i \), and \( \psi_i(z) \) as a function of \( z \) for \( F = 0 \), \(-15 \) (kV/cm), and \(+15 \) (kV/cm), respectively. These figures illustrate the schematic changes in the distributions of \( \psi_i(z) \) due to \( F \) relative to the interface planes \( I_1 \) and \( I_3 \) and the delta-doped layers (lying at \( z = (b/2 + w + s) \)) which effect the scattering potentials.

In Figs. 5, we present the variation in both \( \mu^\text{imp}_i \) and \( \mu^\text{IR}_i \) (cm\(^2\)/Vs) with increase in \( F \) (kV/cm) along the negative \( z \)-axis. As long as two subbands are occupied, \( \mu^\text{imp}_i \) is due to the mixed contributions of intrasubband \( \mu^\text{imp}_i \) and intersubband \( \mu^\text{IR}_i \) scattering rate matrix elements. In Figs. 6 and 7, we plot \( \mu^\text{imp}_i \), \( \mu^\text{IR}_i \), \( C^\text{imp}_i \), and \( D^\text{IR}_i \) to illustrate the dependence of \( \mu^\text{imp}_i \) on the electric field in Fig. 5. As \( F \) increases \( E_{F1} \) decreases and becomes almost zero near \( |F| \approx 9 \) kV/cm (Fig. 1). This leads to a sharp enhancement in \( B^\text{imp}_{11} \) (the value of \( B^\text{imp}_{11} \) near \( |F| \approx 9 \) kV/cm could not be shown in Fig. 6 as it is beyond the scale) thereby reducing \( \mu^\text{imp}_i \) to zero (Fig. 5). However, no such singularity is observed in \( B^\text{IR}_{01} \) (Fig. 7). The variation in \( B^\text{IR}_{11} \) mainly depends upon the changes in the amplitudes of \( \psi_0(z) \) and \( \psi_1(z) \) at the interface planes \( I_1 \) and \( I_3 \) mediated by the dielectric screening matrix. Regarding the variation in \( B^\text{imp}_{00} \) in Figs. 6 and 7, a sudden drop in \( B^\text{imp}_{00} \) occurs near \( |F| \approx 9 \) kV/cm while \( B^\text{IR}_{00} \) exhibits a monotonic decreasing trend with increase in \( F \). In the expression for \( B^\text{IR}_{00} \), the integrand in the right hand side of Eq. (11) contains \( (1 - \cos \theta) \) which cancels with the \( q^2 \) factor occurring in the denominator of \( V^\text{imp}_i(q) \) (Eq. (16)). Therefore the drop in \( B^\text{imp}_{00} \) is mainly due to the discontinuity of the inverse dielectric screening function matrix near the transition from the double subband occupancy to single subband occupancy. However, in the case of \( B^\text{IR}_{00} \) there is no such cancellation. Hence the occurrence of the weight factor \( (1 - \cos \theta) \) in the integrand almost compensates the change in the dielectric screening matrix resulting a monotonic decrease in \( B^\text{IR}_{00} \).

From Figs. 6 and 7, we further note that for small \( F \), the intersubband scattering rate matrix elements \( C^\text{imp}_{01} \) and \( D^\text{IR}_{01} \) are dominant. Therefore the largest contribution to subband mobility \( \mu^\text{IR,imp}_i \) (in Fig. 5) mainly derives from the intersubband interaction terms, i.e., \( C^\text{imp}_{01} \) and \( D^\text{IR}_{01} \). As
$|F|$ increases both $C_{01}^{\text{imp}}$ and $D_{01}^{\text{imp}}$ first decrease sharply and then slowly because of the change in the overlapping of $\psi_0(z)$ and $\psi_1(z)$. For $|F| > 5 \text{ kV/cm}$, $\mu_i^{\text{imp}}$ is dominated by the intrasubband scattering rate $B_{00}^{\text{imp}}$. Whereas, $\mu_0^{\text{IR}}$ is dominated by $C_{01}^{\text{IR}}$ up to $F=9 \text{ kV/cm}$, i.e., for the entire range of double subband occupancy. The large increase in $\mu_i^{\text{imp}}$ (in Fig. 5) is due to the sudden drop in $B_{00}^{\text{imp}}$ (Fig. 6), while that of $\mu_0^{\text{IR}}$ (Fig. 5) is due to suppression of $C_{01}^{\text{IR}}$ and $D_{01}^{\text{IR}}$ (Fig. 7) i.e., the intersubband interaction during the transition to single subband occupancy.

In Fig. 8, we present the variation in $\mu_i^{\text{imp/IR}}$ ($\text{cm}^2/\text{V s}$) with $F$ (kV/cm) along the positive z-axis and compare that in Fig. 5 where $F$ is directed along the negative z-axis. We note that in both the cases the magnitudes of $\mu_i^{\text{imp}}$ remain unchanged. This is because the effect of ionized impurity scattering on the subband electrons is from the ionized donors lying in two delta-doped layers symmetrically placed in the side barriers. Therefore the net effect of the scatterers remains invariant with the direction of the electric field. However, in the case of $\mu_0^{\text{IR}}$, the IR scattering potential is considered to be due to the interfaces ($I_1$ and $I_2$) lying toward the substrate side of the structure.30–32 Therefore $\mu_0^{\text{IR}}$ differs according to the direction of the electric field $F$. As $|F|$ varies from 0 to 9 kV/cm, $\mu_0^{\text{IR}}$ remain almost unchanged in Fig. 8, while it becomes about four times larger in Fig. 5.

In Fig. 9, we plot $B_{00}^{\text{IR}}, B_{11}^{\text{IR}}, C_{01}^{\text{IR}}$, and $D_{01}^{\text{IR}}$ as functions of $F$ along the positive z-axis. The change in $\mu_0^{\text{IR}}$ in Figs. 5 and 8, is attributed to the changes in $C_{01}^{\text{IR}}$ and $B_{00}^{\text{IR}}$ in Figs. 7 and 9, respectively.

In order to calculate the electron mobility $\mu$, we first calculate the mobility limited by the ionized impurity scattering $\mu_i^{\text{imp}}$ and IR scattering $\mu_0^{\text{IR}}$ by using Eq. (8). The mobility is then calculated using the relation $1/\mu = 1/\mu_i^{\text{imp}} + 1/\mu_0^{\text{IR}}$ and plotted in Figs. 10 and 11 for $F$ along the negative z-axis and positive z-axis, respectively. As long as both the subbands are occupied, $\mu$ increases monotonically with $|F|$. For $|F|=9 \text{ kV/cm}$, $\mu$ is about 2.7 times and 1.5 times larger in magnitude in Figs. 10 and 11, respectively compared to the value of $\mu$ at $|F|=0$. As soon as the occupancy of second subband ceases, a sudden enhancement in $\mu$ occurs at $|F|=10 \text{ kV/cm}$. In case of Fig. 10, the enhancement in $\mu$ is around 10 times while for Fig. 11, the enhancement is 5 times the magnitude of $\mu$ at $|F|=0$. In Fig. 10, the large enhancement in mobility is because of the displacement of the lowest subband electron wave function $[\psi_0(z)]$ away from the interface planes $I_1$ and $I_2$ due to the application of the electric field along the negative z-axis.

Normally the IR scattering dominates mobility in quantum wells having narrow well widths.22–24 However, in Fig. 11, even for $w=100 \text{ Å}$, $\mu$ is mostly dominated by IR scattering. The dominance of IR scattering on mobility in quantum wells of larger well widths is due to the displacement of subband wave functions by applying an electric field.

We note that we have not considered the effect of alloy...
disorder scattering on mobility as this effect is small in GaInP/GaAs wells due to the small barrier height and lower alloy disorder potential. The estimated contribution of the effect of the alloy disorder scatterings from the adjacent barriers and also the central barrier of the GaInP/GaAs double quantum well structure to subband mobility is less than 5%. It would be interesting to compare our results of effect of electric field on $\mu_i$ with experimental results for coupled quantum well systems, when such become available.

**IV. SUMMARY**

To summarize, we have made a systematic analysis of the effect of electric field on multisubband electron mobility in a Ga$_{0.3}$In$_{0.7}$P/GaAs double quantum well structure in which the side barriers are delta-doped with Si. We have studied the dependence of the intrasubband and intersubband scattering rate matrix elements on the electric field strength by considering the IR and ionized impurities scattering mechanisms. So long as two subbands are occupied, the mobility is mostly governed by the intersubband effects. At a certain applied electric field the system undergoes a transition from double subband to single subband occupancy thereby exhibiting a sudden enhancement in mobility due to vanishing of the intersubband interaction. We show that by reversing the direction of the electric field, the mobility due to ionized impurity scattering $\mu_{imp}^{IR}$ remains unaffected because the delta-doped layers are placed symmetrically in the side barriers. However, the value of $\mu_{imp}^{IR}$ varies due to the asymmetric nature of the IR potential. We note that normally the mobility is governed by the IR scattering for quantum wells of narrow well widths. However, it is interesting to obtain the mobility dominated by the IR scattering in a quantum well of larger well widths by applying the electric field. Our analysis of the electron mobility for the coupled GaInP/GaAs quantum well system can be utilized for a variety of low temperature devices incorporating such double quantum wells.

**ACKNOWLEDGMENTS**

One of the authors (T.S.) is thankful to the Commonwealth Scholarship Commission, U.K. and the University Grants Commission, India for award of a Commonwealth Academic Staff Fellowship-2008. The work was carried out at the School of Electronic Engineering, Bangor University, Wales, United Kingdom during the visit of T.S. under the above program.
